Design & Strategy: Jennifer

THE PROBLEM

The real cost of running support with no visibility into status.

Across scattered channels — email, WhatsApp, spreadsheets — the agent rebuilds context for every ticket, and the manager decides based on gut feeling, not data. In practice: longer handling times, service quality that depends on the agent, and no reliable metric to justify hiring or process changes. This isn't a support problem — it's a business decision being made without a real tool to support it.

OUR SOLUTION

One single inbox.

A support inbox screen that brings every conversation into one view, with filters by priority (high/low), wait time (longest/shortest) and status (open, pending, escalated). Each conversation shows a short summary, so the agent can understand the context fast before opening the ticket; clicking it opens the full conversation together with the customer profile, joining history and support into a single flow. The goal is to cut triage time and standardize how tickets get prioritized, instead of leaving it to each agent's own judgment.

Theory behind it: John Sweller's cognitive load theory — poorly designed interfaces waste limited processing capacity on things that aren't the actual work.

PERSONAS

Who uses the product

Support agent

Handles tickets every day. Needs to see priority, history and customer context without switching screens or relying on memory from past cases.

End customer

Opens the ticket. Expects a fast reply and doesn't want to repeat the problem on every new contact — wants to feel like someone already knows who they are.

RESEARCH & DATA

Real data replacing guesswork in team management.

Daily volume, average response time and workload per agent, all on the same panel — the same continuous-discovery logic Teresa Torres talks about: product and operations decisions backed by real usage evidence, not by the opinion of the most experienced manager in the room.

AI IN THE PRODUCT — A PRODUCT PROPOSAL, NOT A BUILT FEATURE YET

AI-assisted prioritization for the ticket queue.

The pain point: managers and agents still decide priority "by feel". The idea: an assistant that reads the ticket's context (customer history, keywords, time in queue) and suggests a priority and a first reply — the agent always confirms before sending. Flow: ticket comes in → AI reads context and history → AI suggests priority and a draft reply → agent reviews and confirms.

AI SUGGESTION

Ticket #1082 looks critical: Enterprise customer, 3rd attempt in 24h. I suggest escalating and using the reply below.

[Escalate](#) [Use draft](#)

"Hi, I can see your payment import failed again — I've already sent it to the technical team with high priority."

UX DECISION

A queue prioritized by status, always visible.

The agent never has to ask "what's going on with this ticket" — they just see it. The queue removes manual triage: the next ticket is chosen by looking, not by searching.

Heuristic 1 — Visibility of system status. NN/g — Visibility of System Status.

UX DECISION

History and status always in view, never rebuilt from scratch.

Recognizing is cheaper than recalling. A customer panel, with history and status always shown in the conversation, takes the load off the agent's memory and puts it on the interface instead, where it costs less to process.

Heuristic 6 — Recognition rather than recall. NN/g — Memory Recognition and Recall in User Interfaces.

UX DECISION

The dashboard's metrics are the metrics the manager actually uses.

Volume, response time and workload per agent show up exactly the way the manager already thinks about them — with no technical translation in between. The dashboard speaks the same language as the business decision.

Heuristic 8 — Match between system and the real world. NN/g — 10 Usability Heuristics for User Interface Design.

UX DECISION

Customer history without digging through screens.

Switching screens costs time and breaks concentration. The customer list is one click away, with ticket count and last contact visible — the agent never has to leave the queue to understand who's on the other side.

Heuristic 7 — Flexibility and efficiency of use. NN/g — 10 Usability Heuristics for User Interface Design.

PROCESS

Project timeline

STYLE GUIDE

Functional color palette by status

Colors used for badges, filters and dashboard bars — pulled directly from the real product interface, each ticket status keeps a fixed color, recognizable on every screen.

Manrope — headings in medium weight - Manrope — body text in regular weight.

RESULTS & LEARNINGS

Less time wasted, safer decisions, clearer support.

01 Faster response time A queue prioritized by status removes manual triage — the agent picks the next ticket by looking, not by searching.	02 Consistent service across agents Shared status, history and profile remove the dependency on individual knowledge — quality no longer depends on who answers.	03 Safer management decisions Volume, response time and workload per agent, once invisible, become a management indicator backed by data, not by gut feeling.
